## PART I SATURATED SOILS: TRANSIENT FLOW

# V-I INTRODUCTION, PORE PRESSURE PARAMETERS AND UNDRAINED SHEAR

Page No

## 1. Introduction

1

- Example of storage tank → pertinent issues of stability & settlement

## 2. Skempton's Pore Pressure Parameters

### 2.1 Background

2

### 2.2 B Parameter ( $B = \Delta u / \Delta \sigma_c = \Delta u / \Delta \sigma_3$ )

2

- Test procedure • Physical interpretation • Typical values

### 2.3 A Parameter [ $A = (\Delta u - \Delta \sigma_3) / (\Delta \sigma_1 - \Delta \sigma_3)$ ]

4

- Definition & discussion • Values for elastic material (Fig I-1)
- $ESP = f(A)$  for CIU tests

## 3. Types of Shear Tests, Strength Principles And Undrained Shear Behavior

### 3.1 Types of Shear Tests

6

- CD = Consolidated-Drained • CU = Consolidated-Undrained
- UU = Unconsolidated-Undrained

### 3.2 Statement of Strength Principles

7

- I Unique  $q_f$  vs  $p_f$  • II Unique  $w_f$  -  $q_f$  -  $p_f$  • Applies CD, CU & UU tests

### 3.3 Comparison of CIU vs CID Standard TC Tests Run on NC Clay

7,8

- Fig I-2 and related discussion

### 3.4 Comparison of CIUC(U) vs CIUC(L) for $B=1.00$ ( $S=100\%$ )

9

### 3.5 Undrained vs Drained Shear at High OCR

10,11

- Fig I-3 and related discussion

### 3.6 Effect of OCR on CIUC Stress-Strain-Strength Behavior

10

- Normalized stress-strain & ESP •  $s_u / \sigma'_c$  vs OCR • Analogy with sands

### 3.7 Three Factors Controlling $s_u$

12

- Why  $s_u / \sigma'_c$  increases with increasing OCR

### 3.8 Summary of CIU Strength Parameters vs OCR

13

### 3.9 SHANSEP Equation: $s_u / \sigma'_c = S(OCR)^n$

13

### 3.10 Predict UUC Results from CIDC Test Data

14,15

- Fig I-4 and related discussion

### 3.11 Comments on UUC Testing

16

1. INTRO. (Continued)

4) Long term (drained) stability

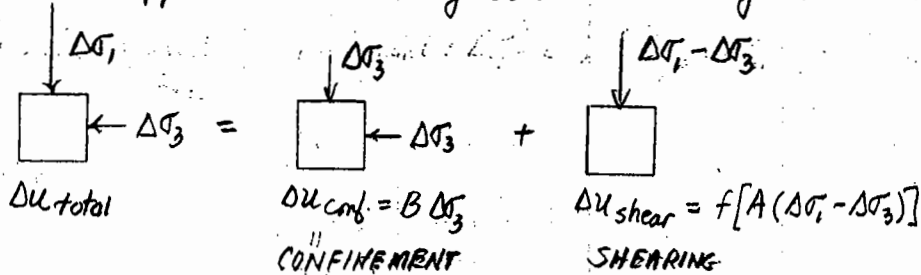

- Analysis covered in Parts IV-6 & 7
  - Never critical for **LOADING**: (Applied stresses increase in situ p)
  - But usually critical for **UNLOADING** (Applied stresses decrease in situ p)
- } Part IV-3

2. SKEMPTON'S PORE PRESSURE PARAMETERS (Chap 26)

2.1 Background

$\Delta\sigma_1 = \Delta\sigma_v$  ;  $\Delta\sigma_3 = \Delta\sigma_h$

- $\Delta\sigma$  = applied stresses during undrained loading: Illustrated for  $\sigma$  element

- For  $S < 100\%$   $\Delta u = B \Delta\sigma_3 + B \cdot A (\Delta\sigma_1 - \Delta\sigma_3)$
- For  $S = 100\%$   $\Delta u = \Delta\sigma_3 + A (\Delta\sigma_1 - \Delta\sigma_3)$  since  $B = 1.00$

NOTE: Above for applied  $\Delta\sigma_1$  ;  $\Delta\sigma_3$ , which can act in any direction. Also can have negative values of  $\Delta\sigma_1$  ;  $\Delta\sigma_3$  (i.e. for UNLOADINGS)

2.2 B Parameter [for hydrostatic (isotropic) compression]

1) Test apparatus and results ( $S \leq 100\%$ )

Triaxial Cell: No Drainage ( $\Delta mass = 0$ )

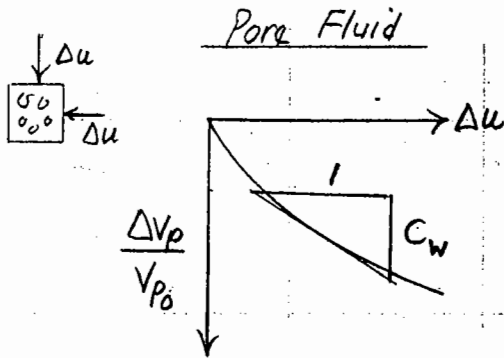

$\Delta\sigma_c = \Delta$  cell pressure =  $\Delta\sigma_3$   
 $B = \frac{\Delta u}{\Delta\sigma_c} = f(\Delta\sigma_c)$

2.2 B Parameter (Continued)

2) Physical interpretation: NOTE Volume decrease is positive

$\Delta V = \Delta V_p \text{ (pore fluid)} = \Delta V_{sk} \text{ (soil skeleton)}$

Soil Skeleton  
Hydrostatic (isotropic)  
consolidation in triaxial cell

$C_w = \frac{\Delta V_p / V_{p0}}{\Delta u} = \frac{\Delta V_p / n V_0}{\Delta u}$

For  $S=100\%$   $C_w = 46 \times 10^{-6} \text{ cm}^2/\text{kgf}$   
 $= 47 \times 10^{-6} \text{ bar}^{-1}$

$C_{c3} = \frac{\Delta V / V_0}{\Delta \sigma'_c}$

$\Delta V_p = \Delta V_{sk} = \Delta V$

$\Delta u \cdot C_w \cdot n V_0 = \Delta \sigma'_c \cdot C_{c3} \cdot V_0 \rightarrow \Delta u C_w n = (\Delta \sigma'_c - \Delta u) C_{c3}$

$\rightarrow \Delta u (n C_w + C_{c3}) = \Delta \sigma'_c C_{c3}$

$B = \frac{\Delta u}{\Delta \sigma'_c} = \frac{1}{1 + n \frac{C_w}{C_{c3}}}$

NOTE: (1) Reliable eqn.

(2) Also valid for 1-D loading

since  $C_{c1} = C_{c3}$ , where  $C_{c1} = m_v = \frac{\Delta E_v}{\Delta \sigma'_v} = \frac{0.434 (Cr \text{ or } Cc)}{(1+E_0) \sigma'_v \text{ ave.}} = \frac{0.434 (RR \text{ or } CR)}{\sigma'_v \text{ ave.}}$

3) Typical values (Table 26.1)

Material	% S	B	Remarks
Soft → stiff CLAY	100 ≈ 99	0.999+ Signif. < 1	• Measure B to check saturation of triaxial specimens • Need back pressure of several atm → S=100% of "sat." clay
Dense SAND	100	0.99	
ROCK	100	< 0.6	• Moderate $\Delta \sigma'_c$
Compacted CLAY	90	0.5 ± 0.2	• Very approximate & increases with $\Delta \sigma'_c$

2.3 A Parameter (Continued)

4) Effective Stress Paths (ESP) as f(A) for CIU Triaxial Tests } Very Important }

For LOADING tests ( $\Delta\sigma_3 = 0$ ):  $\Delta u = p - p' \rightarrow A = (p - p') / 2 | \Delta q |$

Undrained Shear = Superposition of Loading + Unloading Drained Shear

$$\Delta V/V_0 = 0 = C_c (\Delta\sigma_1' - \Delta u) + C_s (\Delta\sigma_3 - \Delta u) \rightarrow \Delta\sigma_1' - \Delta u = (C_s/C_c) (\Delta u - \Delta\sigma_3)$$

Subtract  $\Delta\sigma_3$  both sides & rearrange  $\rightarrow (\Delta\sigma_1' - \Delta\sigma_3) = (\Delta u - \Delta\sigma_3) (1 + C_s/C_c)$

$$\therefore A = \frac{\Delta u - \Delta\sigma_3}{\Delta\sigma_1' - \Delta\sigma_3} = \frac{1}{(1 + C_s/C_c)}$$

### 3. TYPES OF SHEAR TESTS, STRENGTH PRINCIPLES AND UNDRAINED SHEAR BEHAVIOR

#### 3.1 Types of Shear Tests (S ≈ 100%)

- Will define three basic types of triaxial shear tests that can be run on "undisturbed" samples of clay

- Steps during testing

① Initial condition after trimming specimen and placing in cell ( $\sigma_c = 0, w_i = w_N$ )

$$\sigma'_s = \sigma_c - u = -u \quad \text{Capillary pressure } u_c = u_a - u_w$$

② Apply  $\sigma_c$  (with or w/o drainage)    ③ Apply  $\sigma_1 - \sigma_3$  (with or w/o drainage)  
(May have  $K_c \neq 1$ )

#### 1) Consolidated-Drained = CD

back pressure to saturate

• C = consolidated wrt  $\sigma'_c = \sigma_c - u_b \rightarrow \Delta v \therefore w_c \neq w_N$

• D = drained during shear  $\rightarrow \Delta u = 0 \quad \Delta w \neq 0$

Examples CIDC/E (L/U)    CK<sub>0</sub>DC/E (L/U)

$I, K_0 = K_c = \sigma'_{hc} / \sigma'_c$   
C, E = Comp., Ext.  
L, U = Load, Unload

#### 2) Consolidated-Undrained = CU

• C = as above with  $\sigma'_c = \sigma_c - u_b \quad w_c \neq w_N$

• U = undrained during shear  $\rightarrow \Delta w = 0, \Delta u \neq 0$   
 $w_f = w_c$

Usually need  $u_b =$   
Several atm.  $\rightarrow$   
 $S = 100\% \rightarrow B = 1.00$

Examples CIUC/E (L/U)    CK<sub>0</sub>UC/E (L/U)

Measurement of  $u$  is standard practice

NOTE: For both CD & CU tests, automated triaxial equipment can follow any stress path during consolidation (i.e., 1-D =  $K_0$ ) and shear

#### 3) Unconsolidated-Undrained = UU

• 1<sup>st</sup> U = unconsolidated wrt  $\sigma_c$ , i.e., no drainage allowed

$$\text{Prestress } \sigma' = \sigma'_s + \sigma_c - \Delta u = \sigma'_s + \sigma_c (1 - B)$$

Hence  $w_f = w_N$

• 2<sup>nd</sup> U = as above (except usually do not measure  $u$ )

- Std practice = triaxial compression (loading)  $\equiv$  UUC with  $d\varepsilon_a/dt = \dot{\varepsilon}_a = 1\%/min$

- If  $\sigma_c = 0$ , then call

### 3.2 Statement of Strength Principles

- For NC (OCR=1) clay or OC clay with same  $\sigma'_{cm}$  } But treat TC and assuming no sample disturbance: }  $\frac{1}{2}$  TE Separately

- I Unique failure envelope, i.e.  $q_f$  vs  $p_f$  } Applied to all 3 types of
- II Unique  $w_f - q_f - p'_f$  relationship } triaxial tests, i.e. CP, CU, CU
- (that is parallel to  $VCL = w_c \approx \log \sigma'_c$ )

• Will also assume perfect normalized behavior wrt  $E_a \approx \frac{(\sigma_1 - \sigma_3)}{\sigma'_c}$ ,  $\Delta w$ ,  $A$ , etc.

### 3.3 Comparison of CIU vs CID Standard TC Tests Run on NC Clay

- See Fig. II-2 (p8) for results of a CIDC(L) test run on clay with linear VCL and normalized behavior. Hence only 1 test needed to define Princ. I & II relationships

- Will now illustrate how one can predict either exact or approximate stress-strain-strength properties for a CIUC(L) test starting from the same  $\sigma'_c = \sigma'_c - u_b$ .

a) Values of  $s_u = q_f$  and  $p'_f$  from Principle \_\_\_\_\_ = \_\_\_\_\_

(Note: Typical  $s_u / \sigma'_c = 0.30 \pm 0.05$ )

b) Total Stress Path (TSP)  $\frac{1}{2}$  TSP -  $u_b =$  \_\_\_\_\_

c) End point for Effective Stress Path (ESP) = \_\_\_\_\_

d) ESP for  $A = 0$  &  $1.0$

- Initial  $A$  for elastic response = \_\_\_\_\_

- Typical  $A_f$  for OCR=1 =  $1.0 \pm 0.2$

• Typical shape of ESP and determination of  $A$

e) Stress vs strain  $\rightarrow E_f = 5-10\%$

- $E_a \approx \frac{(\sigma_1 - \sigma_3)}{\sigma'_c}$ ,  $\Delta u / \sigma'_c \in A$

- $\Delta \sigma'_3 = \Delta \sigma_3 - \Delta u =$  \_\_\_\_\_  $\times (\sigma_1 - \sigma_3)$

- $\Delta \sigma'_1 = \Delta \sigma_1 - \Delta u =$  \_\_\_\_\_  $\times (\sigma_1 - \sigma_3)$

Shape of ESP is uniquely related to values of  $A$

3.5 Undrained vs. Drained Shear at High OCR (Fig. II-3, p11)

1) Review of CIDC behavior for OC clay

a) Summary re NC

- Increase in ESE ( $q_f$  re  $p_f$ ): Principle I
  - $w_f - q_f - p_f$  shifts to left with increasing OCR: Principle II
- } same for CIDC & CIUC

b) Review CIUC(L) data at OCR = 10 in Fig. II-3 (p11)

- Clay behavior at high OCR similar to "dense" sand (negative  $\psi$  Part III-2 large  $I_R$ )

2) Predict - compare CIUC(L) & CIDC(L) at OCR = 10 (same  $\sigma_{cm}'$  &  $\sigma_c'$ )

- How obtain  $q_f$  &  $p_f$ ?
- How predict shape of  $E_a \text{ re } (\Delta u - \Delta \sigma_3) / \sigma_c'$ ?
- Resultant shape of  $E_a \text{ re } (\sigma_1 - \sigma_3) / \sigma_c'$   
" " " " " " A
- Resultant shape of ESP, value of  $w_f$ , etc.

3) What changes if run CIUC(U) test at same  $\sigma_c'$  &  $\sigma_{cm}'$ ?

3.6 Effect of OCR on CIUC Stress-Strain-Strength Behavior

1) Normalized Stress-Strain Curves

Increasing OCR  $\rightarrow$

- Increasing stiffness ( $E_u / \sigma_c'$ )
- "  $s_u / \sigma_c'$
- "  $E_f$
- Decreasing  $(\Delta u - \Delta \sigma_3) / \sigma_c'$

 Made in U.S.A.

Fig. V-1-3 CIDC(L) vs. CIUC(L) at OCR=10

3.6 Cont.

2) Normalized Effective Stress Paths

- Increasing OCR → Contractive behavior  $\left\{ \begin{array}{l} \text{CD Tests} \\ \text{Dec. vol} \end{array} \right.$   $\left\{ \begin{array}{l} \text{CU Tests} \\ \text{Dec. } p' \end{array} \right.$   
 ↓  
 Dilatant behavior  $\left\{ \begin{array}{l} \text{Inc. vol} \\ \text{Inc. } p' \end{array} \right.$
- Very similar to sand behavior covered in Part III-2  
 +  $\psi$  or low  $I_R$  (low OCR) → contraction  
 -  $\psi$  or high  $I_R$  (high OCR) → dilation

3) Undrained Strength Ratio,  $s_u/\sigma'_c$

3.7 Three Factors Controlling  $s_u$  (For CIUC or CIUE)

- 1) Initial  $p' = \sigma'_c$
- 2)  $\Delta p'$  during shear =  $f(\quad)$
- 3)  $q_f$  per  $p'_f = f(\quad)$

$$\frac{q_f}{\sigma'_c} = \frac{c' \cos \phi' / \sigma'_c + \sin \phi'}{1 + (2A_f - 1) \sin \phi'}$$

$\left\{ \begin{array}{l} \text{Sheet (A) of} \\ \text{II-4 derived for} \\ \text{all } c' \text{ and } \phi' = 0 \end{array} \right.$

Which is more important in explaining why increasing OCR → much larger  $s_u/\sigma'_c$ ?

### 3.8 Summary of CIU Strength Parameters vs. OCR

1) CIUC trends with log OCR

Notes: Extensive data from CIU & CKU tests on wide variety of clay → linear  $\log s_u/\sigma'_{vc}$  vs  $\log OCR$  (see Part II-4)  
 • Plot drawn for  $S=0.33$  &  $m=0.8$

### 3.9 SHANSEP Equation (SHANSEP = Stress History And Normalized Soil Eng. Properties) Ladd & Foott (1974), JGED, 100(9) Ladd (1991) JGE 117(4)

1)  $\log s_u/\sigma'_c = \log S + m \log OCR$  from above (Use  $s_u/\sigma'_{vc}$  for CKU tests)

$\therefore s_u/\sigma'_c = S(OCR)^m$  Must know how to apply (more details in Part II-4)

$S = s_u/\sigma'_c$  at  $OCR = 1$   
 $\approx 0.3 \pm 0.05$  for CIUC  
 $\approx 0.2 - 0.25$  for CIUE (high  $A_f$ )

$m = (d \log s_u/\sigma'_c) / d \log OCR$   
 $\approx 0.8 \pm 0.1$  for most clays

2) Section II-4 will show that for undrained stability analyses of loads on saturated clay:  $S = 0.22 \pm 0.03$  &  $m = 0.8 \pm 0.1$

### 3.10 Predict UUC Results From CIUC Test Data

- 1) Objective: To further illustrate application of Principles I & II
- 2) Given: Following data from one CIUC test run with  $\sigma'_c = p' = \text{constant}$  on NC clay having  $K_c = 1$  and perfect normalized behavior

• See Fig II-4 (p15) for  $w$  vs  $\log \sigma'_c$  and plotted values of  $w_f$  vs  $q_f$  &  $p'_f$ .

- 3) Make predictions for unconfined compression test (UUC with  $\sigma'_c = 0$ ) run on tube sample with zero disturbance and  $w = w_f$  (see listing in c) of Fig II-4, p15)

NOTE: If you comprehend class discussion, then your understanding of basic strength principles far exceeds that of average practicing geotechnical engineers.

- 4) For this example, UUC test = CIUC test on sample with unknown  $\sigma'_c$  unless one measured preshear  $\sigma'_s$ . Also, this illustration applied to both NC and OC clay.

a) w-log stress (Principle II)

c) Predictions for UC Test (w=wH)

1)  $\sigma'_s = u_c = \sigma'_o$

2)  $P'_f \neq q'_f$

3)  $TSP \neq TSP - \sigma'_o$

4)  $u_f \neq \Delta u_f$

5)  $A_f$

6)  $ESP$

7)  $\epsilon_a \neq q$

b) Stress Paths (Principle I)
